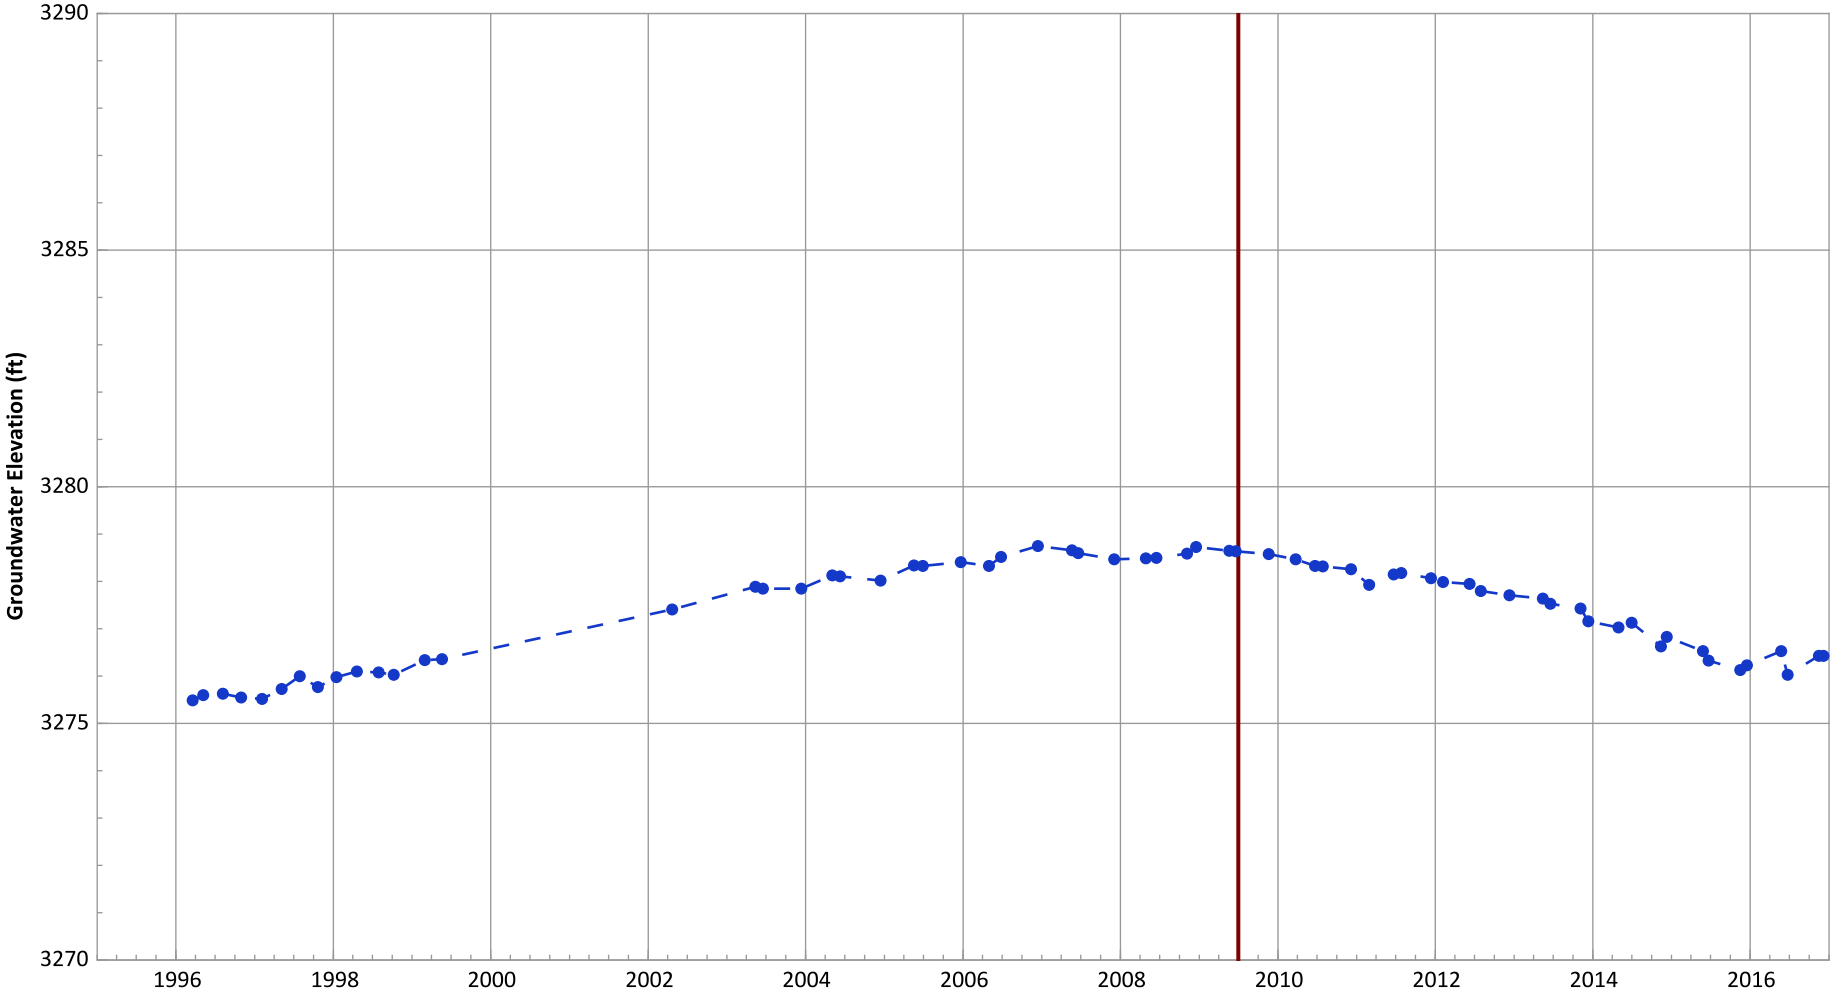
1114-MW4 Hydrograph in Perched Aquifer
USDOE/NNSA Pantex Plant

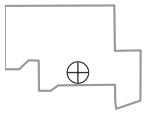


Notes:
1. Top of screen elevation is 3280.32 ft msl.
2. The bottom of screen elevation is 3260.32 ft msl.
3. A continous hydrograph was produced by linear interpolation between successive discrete measurements. Actual groundwater elevations between measurements may be different than shown.

Analysis Date: 02/02/2017

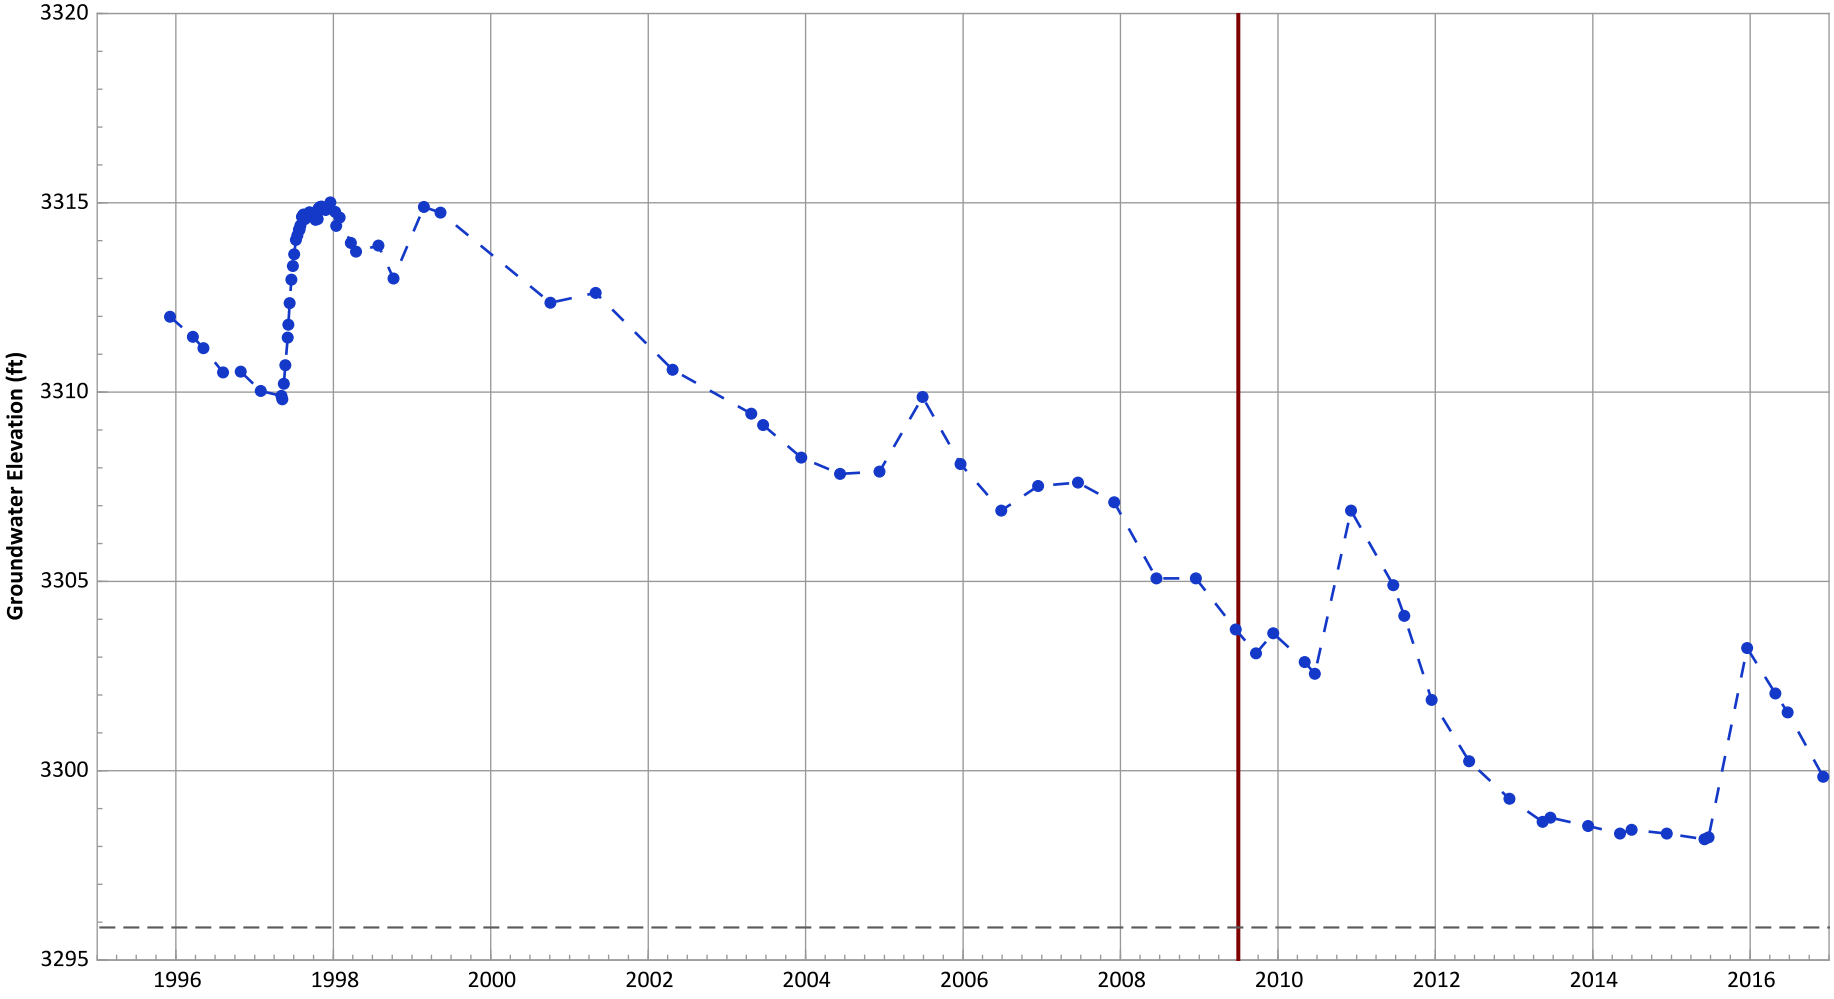
Groundwater Elevation
Start of Remedial Action

Well Location



Hydrograph Trend
(MAROS Linear Regression Method)
Data (7/2009 - 12/2016): Decreasing at 0.36 ft/yr
2014 - 2016 Data: No Trend

OW-WR-38 Hydrograph in Perched Aquifer
USDOE/NNSA Pantex Plant



Notes:
1. Top of screen elevation is 3310.86 ft msl.
2. The bottom of screen elevation is 3295.86 ft msl.
3. A continous hydrograph was produced by linear interpolation between successive discrete measurements. Actual groundwater elevations between measurements may be different than shown.

Well Certifications and Completion Diagrams

U.S. Department of Energy/National Nuclear Security Administration – Pantex Plant
Amarillo, Texas

Certification of Well Construction
Industrial Solid Waste Registration No. 30459
Hazardous Waste Permit No. 50284
EPA Identification No. TX4890110527

Certification Statement:

This is to certify that the construction and plugging and abandonment of the following facility components authorized or required by Texas Commission On Environmental Quality HW-50284 Provision XI Compliance Plan has been completed, and that construction and plugging and abandonment of said components has been performed in accordance with and in compliance with the design and construction specifications of Provision XI Compliance Plan Attachment C of HW-50284:

- Construction of Long-Term Monitoring Observation wells PTX06-1071 (replacement), PTX06-1182, PTX06-1183, PTX06-EW-82, PTX06-EW-83, PTX06-EW-84, PTX06-EW-87, PTX06-EW-88.
- Plugging and abandonment of PTX06-1071 (original) and PTX06-1124 monitoring wells.

			ML	5' - 20' clayey SILT, light reddish brown (5YR 6/4) to dark reddish brown (2.5YR 2.5/4), slightly plastic, dry to damp when clay is prevalent, slightly vesicular with manganese blebs and minor caliche		
			ML	20' - 50' clayey SILT to lean CLAY, reddish brown (5YR 5/4), non- to low plasticity, non-cohesive, dry, spotty caliche and manganese inclusions @ 20' - 30' mainly soft silt @ 35' color change to yellowish red (5YR 5/6), increasing clay as thin lenses, some caliche nodules		
			CL	@ 45' color change to light brown (5YR 6/3) as coatings on clayey chunks to 5 cm @ 47' increasing clay and caliche stringers		
			ML	50' - 55' SILT, pink (5YR 7/4), non-plastic, soft, dry, pebbly caliche to 3 cm		
			SM	55' - 70' silty SAND, yellowish red (5YR 5/8), 30% - 40% silt, fine grain rounded sand, abundant caliche granules to 2 cm, dry		
			SM	70' - 77' silty SAND and Caliche, pinkish white (5YR 8/2), 4 - 5 cm chunks of caliche with silty sand as above		
			SP	77' - 80' SAND, yellowish red (5YR 5/6), 100% clean quartz sand, fine grain, rounded, loose, dry		
			SLT-STN	80' - 88' SILTSTONE, caliche caprock, pinkish white (5YR 8/2), big chunks of caliche with trace fine grain sand		
			SP	88' - 100' silty SAND, pink (5YR 7/4), 60% fine and very fine grain sand, 40% caliche silt and broken caliche to 1.5 cm, dry

Attachment 1: Comparison of 2009 and 2016 Perched Aquifer Groundwater Elevations

I. Introduction

This updated evaluation is included in the 2016 Annual Progress Report as a result of key findings in the First Five-Year Review Report (Pantex 2013). The report recognized that perched groundwater COC plumes continue to move and/or expand downgradient, especially to the east of FM 2373 and in the southeastern lobe of the perched aquifer. As stated in the Groundwater Remedy Effectiveness Evaluation (Trihydro 2012) conducted as part of the First Five-Year Review, portions of these areas are not under the short-term influence of the SEPTS and may not be under the long-term influence because of limited saturated thickness or other limiting hydrogeologic conditions (see Figure 1).

Because of the issues identified, Pantex is evaluating these areas in more detail than prior reporting efforts, which tended to focus more on the operation of installed remedial actions and effects on the perched groundwater system as a whole rather than these areas near the fringe of perched groundwater that may or may not be influenced by the installed remedial actions. This report is the fifth focusing on these areas, and will be updated and revised yearly as part of the Annual Progress Reporting as additional data is collected and analyzed. The 2016 update includes discussion of water level and COC concentration data

Even though several high explosive compounds are found in this region, this report focuses on the RDX plume because it is the most widespread COC occurring at the highest concentrations in these areas and has been consistently used in prior reporting and evaluations to represent the southeast plume. The following sections discuss RDX concentrations, trends, and apparent plume movement in perched groundwater east of FM 2373, along with the effects of pump and treat operations over time.

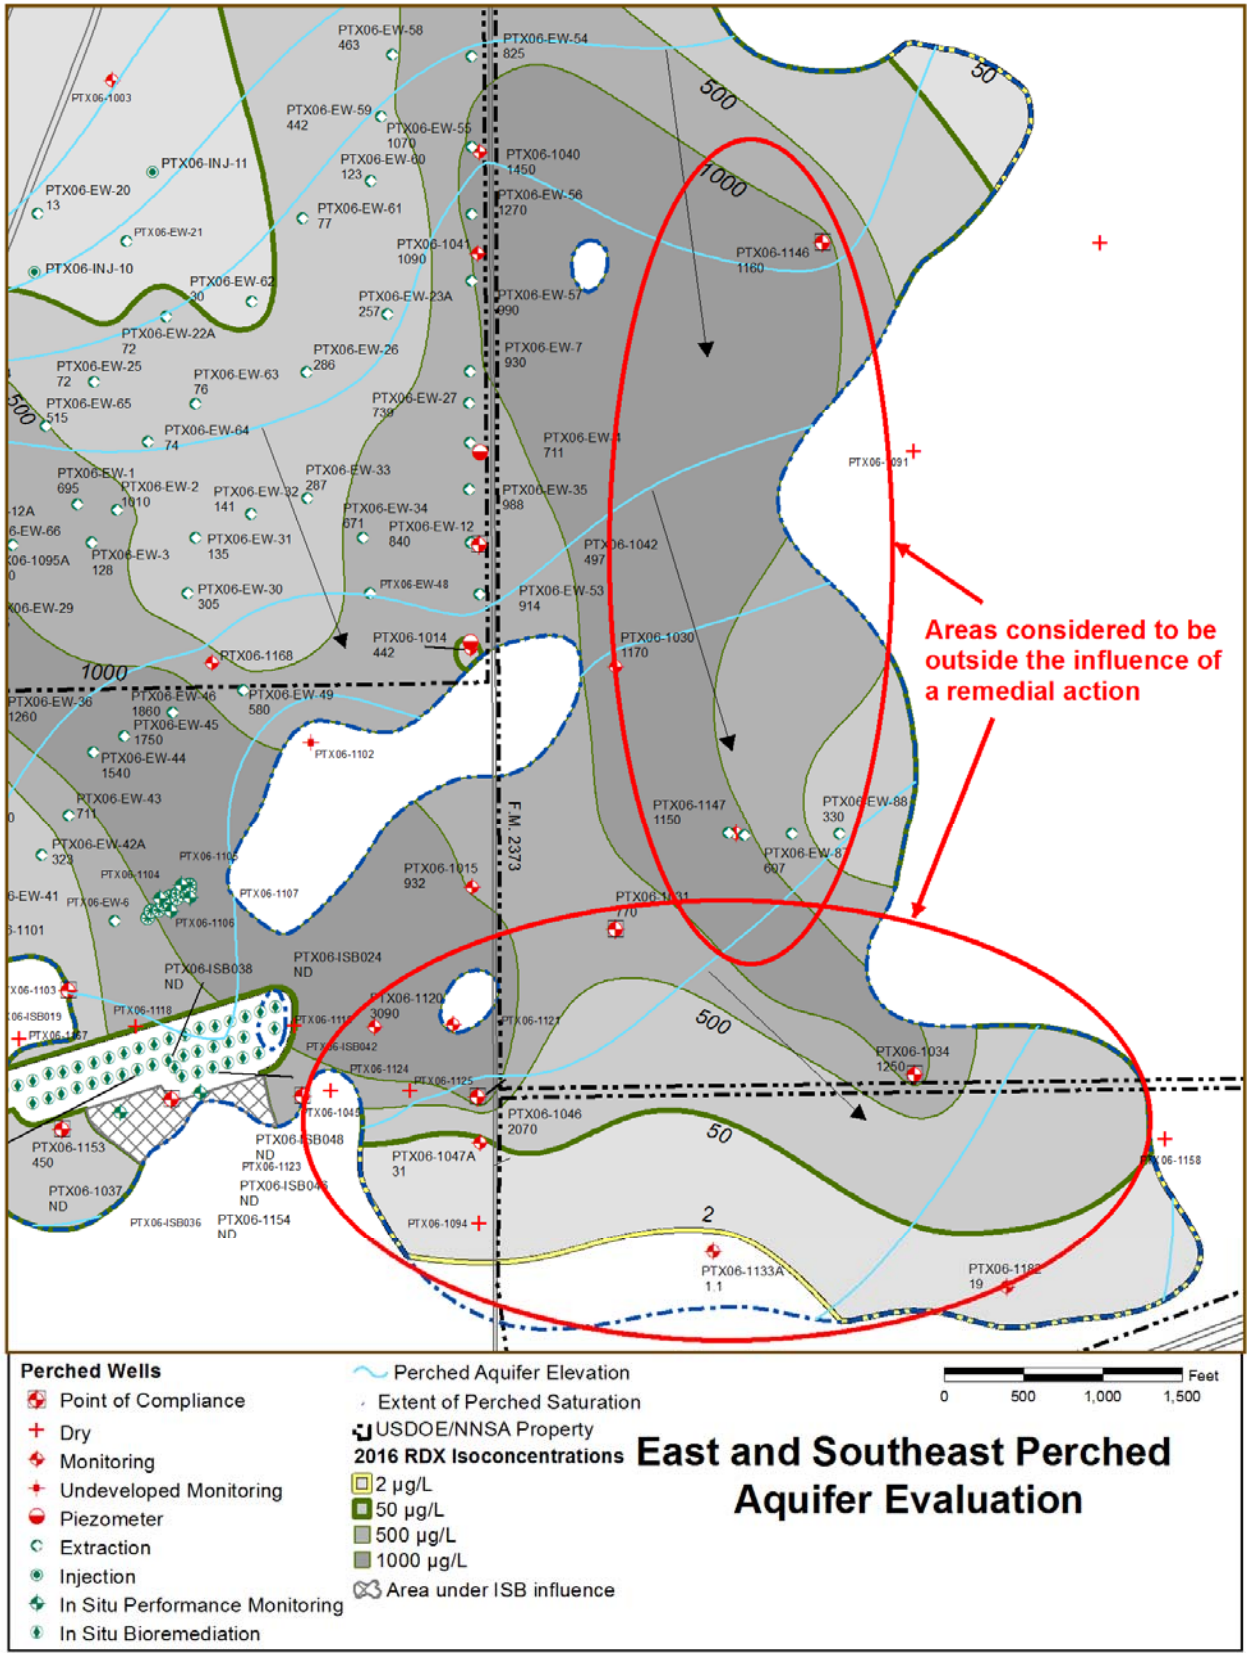

Figure 1. Areas of Perched Groundwater Outside the Influence of Remedial Actions

II. Wells Evaluated

Many wells have been installed in the areas identified as currently outside the influence of a remedial action depicted in Figure 1. These wells are discussed in detail below and include:

- PTX06-1015
- PTX06-1030
- PTX06-1031
- PTX06-1034
- PTX06-1046
- PTX06-1047A
- PTX06-1094
- PTX06-1120
- PTX06-1121
- PTX06-1133A
- PTX06-1146
- PTX06-1147
- PTX06-1182

Additionally, six dry wells are installed in this region of perched groundwater and help define the perched extent. These wells are monitored at least twice per year for water levels and will be included in this evaluation if water is observed in these wells. These dry wells include:

- PTX06-1158
- PTX06-1094
- PTX06-1125
- PTX06-1124[1]
- PTX06-1090
- PTX06-1091

PTX06-1015 was installed in 1995 on Texas Tech property approximately 150 feet west of FM 2373. RDX concentrations in this well have exceeded GWPS since installation and have fluctuated near 1,000 ug/L since 2010. This well is the closest downgradient to the SEPTS extraction well field so it may be the first well to realize effects of extraction. However, an apparently expanding area of very thin perched saturation separates this well from the primary area affected by the SEPTS extraction well field. Water levels in this well have been consistently declining at a rate of about 0.37 ft/year since the start of remedial actions.

[1] PTX06-1124 was plugged and abandoned in 2016. The well was in a location that interfered with construction of the Pantex Administrative Support Center. An evaluation determined that the well was redundant to PTX06-1045 and PTX06-1125 and should therefore be plugged to avoid construction issues and future issues with sampling the well.

PTX06-1030 and PTX06-1031 were installed in 1996 approximately 750 feet east of FM 2373 on the former Cockrell property, which was eventually purchased by DOE in 2008. RDX concentrations in PTX06-1030 have exceeded GWPS since monitoring began in 1996, typically ranging from 500 – 2,000 ug/L. However, a generally decreasing trend in RDX is indicated by the data collected since the start of remedial actions in 2009. PTX06-1031, which was installed approximately 1,700 feet south of PTX06-1030, had non-detect RDX results in 1996 followed by a gradual increasing trend in RDX. The Mann-Kendall statistical evaluation indicates No Trend in the data since the start of remedial actions although empirical evaluation shows a generally increasing trend with a more pronounced increase in samples from 2016. Water levels in both wells are decreasing since the start of remedial actions with recent observations (over the last two years) declining at rates of 0.36 and 0.86 ft/year, respectively.

PTX06-1034 was installed 1998 in the southeast lobe of perched groundwater (former Cockrell property) and was the furthest downgradient sampled well in the area until the installation of PTX06-1182 in 2016. RDX was initially non-detect in this well, but concentrations began to dramatically increase in 2005. After declining slightly in 2015, the RDX concentration increased to the all-time high value of 1,250 ug/L during the second sampling event of 2016. Water levels at this well have declined since the start of remedial actions, but recent data indicate increasing water levels at the rate of 0.29 ft/year. Because of the concern over increasing COC trends in this well, Pantex installed an additional well (PTX06-1158) further east of PTX06-1034 in 2012, but that well has been dry since installation.

PTX06-1046 and PTX06-1047A were installed on Texas Tech property in 2000. RDX concentrations have exceeded GWPS in PTX06-1046 since monitoring began in 2000 and have increased from approximately 500 to over 2,000 ug/L in 2016. RDX was initially non-detect in PTX06-1047A, installed approximately 300 feet south of PTX06-1046, until concentrations rapidly increased in 2006. RDX levels in PTX06-1047A appear to have peaked in 2012 at over 600 ug/L and subsequently dramatically decreased to less than 10 ug/L in 2014. Recent concentrations are increasing with a concentration of 31 ug/L in the most recent sample from 2016. While these trends conflict with the general north-south gradient believed to be driving groundwater movement in the area, the measured concentrations have remained much lower than previous observations for more than two years. Water levels in both wells have been declining at a rate of about 0.4 ft/year since the start of remedial actions.

PTX06-1094 was previously believed to be a dry well. However, based on the recent observations of perched saturation at PTX06-1133A and PTX06-1182, the drilling and construction records for this well were reviewed. With the context provided by surrounding perched water levels as observed at PTX06-1047A and PTX06-1133A, this review determined that the bottom of the screen was set approximately 10 ft above the top of the FGZ. Therefore, perched saturation is likely present at this location with the water table below the bottom of the screen. Therefore, this well was not used to constrain the extent of perched saturation in this area for the 2016 mapping.

PTX06-1120 and PTX06-1121 were installed east of the Southeast ISB system in 2007 and were considered to be dry when completed; however, water appeared in both wells when measured in 2008 and routine sampling commenced in 2010. RDX concentrations have ranged from approximately 2,000 to 4,000 ug/L in PTX06-1120 and from about 800 to 1,300 ug/L in PTX06-1121. RDX data in PTX06-1120 indicate a decreasing trend. PTX06-1121 has not been sampled since 2012 because of insufficient water. Water levels in both wells have been declining at a rate of more than 0.3 ft/year since the start of remedial actions; the water level observed in December 2016 was less than 2 inches above the bottom of the screen in PTX06-1121.

PTX06-1133A was installed in 2008 south of the known extent of perched saturation. The well was initially dry and remained dry until June 2011 when more than 3 ft of water was observed in the well. Saturation continued to be observed in this well until December 2013 when the water level suddenly declined to below the bottom of the screen. Water continued to be detected in the sump of the well until June 2016 when about 2 ft of water was found in the well. RDX was detected for the first time in this well in 2016 at levels below the GWPS.

PTX06-1146 and PTX06-1147 were installed along the eastern edge of the estimated perched extent in 2008. When sampling began in 2009, RDX concentrations in PTX06-1146 were around 1,400 ug/L and increased until early 2011 when the concentrations appeared to have peaked. RDX may now be exhibiting a statistical decreasing trend below 1,200 ug/L in the most recent samples from PTX06-1146. RDX concentrations in PTX06-1147, installed approximately 3,800 feet south/southwest of PTX06-1146, increased from approximately 400 ug/L to over 1,000 ug/L from 2009 through 2013. RDX concentrations significantly decreased during 2014, but have since increased to 1,150 ug/L in 2016. Water levels in both wells are declining at rates of 0.36 and 0.46 ft/year based on data collected during the last two years.

PTX06-1182 was installed in July 2016 outside the known extent of perched saturation in the southeast; however, almost seven feet of saturation was found in this well indicating perched water and contamination have migrated farther to the southeast. RDX was found above the GWPS at 19 ug/L in the second sample collected from this well. No water level trend data are available.

III. Pumping Effects

If the perched groundwater elevation contours are compared from 2009 to 2016 (Attachment 1), positive effects of pump and treat operations are apparent, including the reduction of the mound of groundwater beneath Playa 1 and a general shift of groundwater contours to the north in the SEPTS well field indicating reduction of saturated thickness. Further south, perched groundwater elevation contours have remained constant or actually shifted to the southeast in the extreme southeast lobe of perched groundwater because of the observed increases of saturated thickness in PTX06-1034 and PTX06-1133A along with the new data from PTX06-1182. The other noticeable change in the maps is the apparent spread of the dry zone located south of the SEPTS well field caused by the decline of saturated thickness observed at PTX06-1102,

PTX06-1014, PTX06-1015, and PTX06-1030. This dry zone will likely continue to expand as pump and treat operations continue to reduce saturated thickness of the perched aquifer upgradient of this area.

These observations are also supported by the 2016 Capture Zone analysis results which are depicted in Figure 2. The capture zones represent areas of influence over a five-year pumping period using 2016 well operational data coupled with a single layer groundwater model specifically developed for evaluating remedial options in the perched aquifer. While the area of influence did slightly expand to the east from 2012 to 2016 (likely due to an emphasis on operating the wells along FM 2373 and possible dewatering of the perched aquifer in the extraction well field), a large area to the east remains unaffected by SEPTS system operations.

As recommended in the 2015 Annual Progress Report, Pantex is actively working to extend SEPTS extraction east of FM 2373 to limit further migration of impacted perched water southward along the eastern margin of the perched aquifer. Extending the SEPTS well field to the east across FM 2373 may reduce head and thus groundwater flux before it reaches areas with lower transmissivity where pump and treat technologies are less effective. This action is in agreement with the selected remedy for the southeast perched groundwater. The ROD selected the SEPTS as the final remedy to stabilize migration and treat perched groundwater contaminants. A total of seven potential new extraction wells have been installed east of FM 2373 in a line running east-to-west. Data collected from these wells indicates this is an area of greater saturated thickness than found to the north or south. Contracting for design of the SEPTS extension began in June 2016; the wells in this area should become active by early 2018.

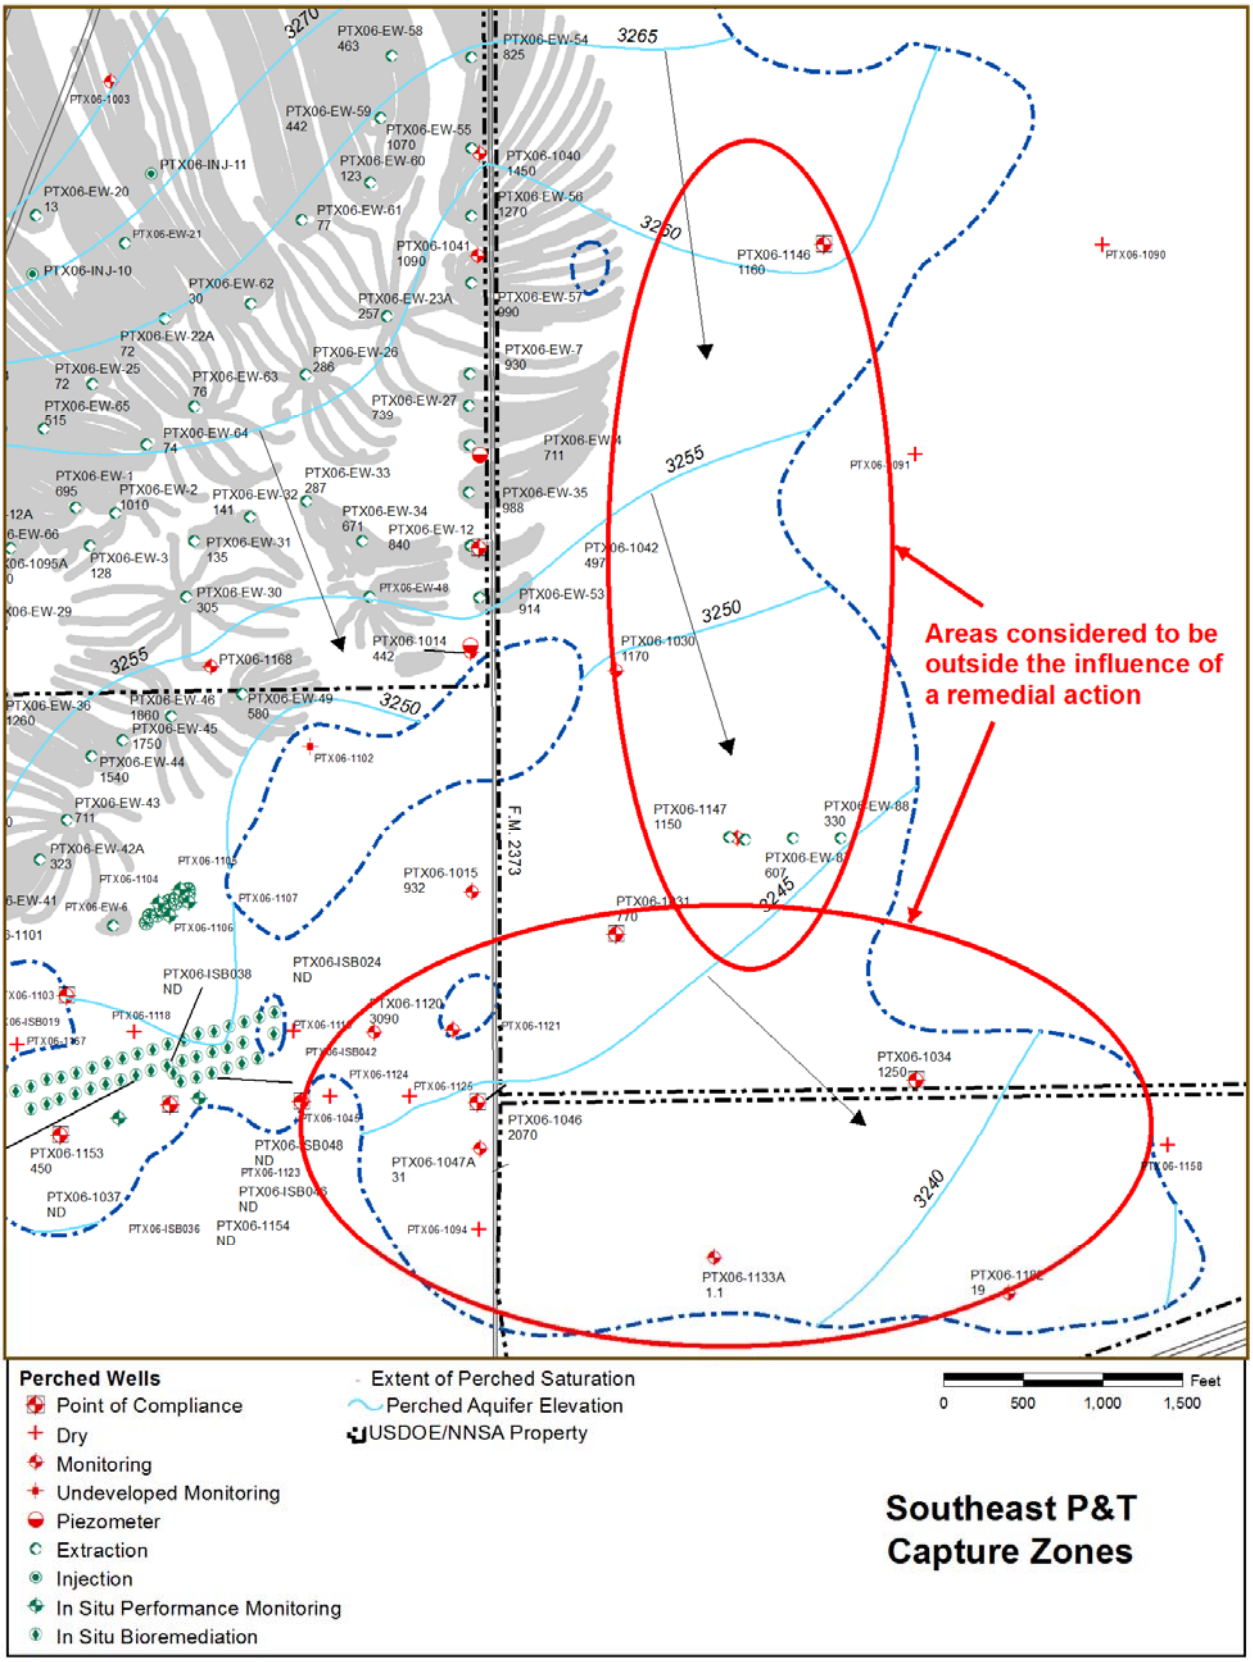

Figure 2. SEPTS Capture Zones

IV. Indicators of Plume Movement

In order to evaluate and attempt to quantify plume movement in the areas that are unlikely to be affected by pump and treat operations, RDX concentrations were plotted over time on the same axis for:

- PTX06-1030
- PTX06-1031
- PTX06-1034
- PTX06-1147

These wells were chosen because they are generally located in a line following the groundwater gradient in the area, which shifts from southerly (in the northern region) to southeasterly (in the southern region).

As depicted in Figure 3, RDX data have been collected in PTX06-1030 and PTX06-1031 since 1996. At that time, the RDX plume had already reached PTX06-1030 because, with the exception of a single data point, the concentrations consistently exceeded 200 ug/L. Concentrations subsequently increased to values ranging around 1,500 ug/L, increased sharply in 2011, and are now exhibiting a somewhat stable trend at about 1,100 ug/L. In PTX06-1031, RDX concentrations were at or near detection limits until 1998, then gradually increased through 2008. RDX was stable around 500 ug/L in this well until 2016, but have recently increased to 770 ug/L.

RDX was non-detect in PTX06-1034, until recently the furthest downgradient sampled well installed in the area, until 2002, then concentrations began to steadily increase. In 2010, concentrations began increasing at a much faster rate and exceeded 1,000 ug/L for the first time in 2016. The rate of increase in concentrations appears to be much faster than the rate at PTX06-1031 and concentrations are now higher than high values observed at PTX06-1031. Therefore, it appears that the RDX detected in PTX06-1034 more likely migrated from the perched groundwater to the east represented by PTX06-1147.

High concentrations of RDX had already reached PTX06-1147 when installed in 2009. Concentrations in this well, installed between PTX06-1030 and PTX06-1034 but shifted to the east, increased from approximately 400 ug/L to over 1,200 ug/L in 2011. Recent data indicate that RDX concentrations are variable in this well.

If the RDX concentration of approximately 400 ug/L depicted on Figure 3 is chosen as representative of the leading edge of the RDX plume and considering the temporal changes in concentration discussed above, the RDX plume appears to be moving downgradient at a rate of 100 to 200 ft/yr from PTX06-1030 to PTX06-1034. This rate of transport appears to be faster than groundwater velocities estimated for the SEISB conceptual site model, but similar to those groundwater velocities estimated for the Zone 11 ISB conceptual site model (Trihydro 2011).

Note that the ISB velocities were estimated using slug testing techniques in ISB injection wells, which may or may not be representative of conditions in the surrounding formation.

PTX06-1133A was dry when installed in 2009 and remained dry until 2011, when approximately 3 feet of water entered the well. Observed water levels subsequently declined through 2013 when the water level dropped below the bottom of the well screen. This well was sampled from December 2011 through May 2013; all VOCs and HEs were non-detect in those samples. Water was again measured in PTX06-1133A in 2016 with about 2 ft of saturation above the bottom of the screen. RDX was detected below the GWPS in both samples collected in 2016.

These water level measurements and analytical results could suggest that the perched extent was slowly expanding in the area and "old" perched groundwater, unaffected by Pantex Plant operations, had now moved into this well. Alternatively, these data could indicate the influence of enhanced recharge following the very high rainfall that occurred in 2010 and again in 2014 through the large borrow pit located further south near U.S. Highway 60. However, because of the fluctuating saturated and dry conditions in this well, it is unknown whether the saturated conditions in the well are caused by an expanding extent of perched groundwater from the north or south, or by some other unknown phenomena. This well will continue to be monitored and will be sampled if sufficient water is available to support sample collection.

PTX06-1182 was installed in 2016 in an area that was previously thought to be beyond the extent of perched saturation; the presence of RDX above the GWPS has been confirmed with the most recent sample showing a concentration of 19 ug/L. This well will continue to be monitored and will provide valuable information on the movement of contaminants in this area of the perched groundwater. Pantex plans to install additional wells downgradient in 2017 to determine perched groundwater and contaminant extent in this area.

As summarized in Figure 4, the wells in the far southeastern lobe of perched groundwater are exhibiting various statistical trends in RDX considering the 2009 – 2016 data. However, as shown in Figure 3, RDX concentrations in these wells are somewhat stable over the past few years. These conditions may be caused by mass removal upgradient and some mixing with unaffected water in the region.

V. Conclusions

The evaluation of data presented in this report lead to several important conclusions. First, given the current configuration of the SEPTS well field, the system will not be able to affect water levels, spread of the perched aquifer, or COC mass currently in the southeast lobe of the perched aquifer. Monitoring data collected since 2008 in wells located within the southeast lobe of the perched aquifer indicate the continued movement of the RDX plume into this area. Water will continue to flow into this area from the north (supported by recent data from PTX06-1034) under the influence of the general hydraulic gradient, increasing both water volume and COC mass, which will likely continue to slowly spread throughout this zone of perched groundwater.

Therefore, several options could be considered for this region depending on the risk associated with COCs exceeding the GWPS in this area. An in-situ treatment technology could be utilized to treat the current mass or encourage natural attenuation processes in the area, or groundwater extraction technologies could be employed. Although sustainable pumping rates are estimated to be low, the installation of extraction wells east of FM 2373 in areas that have a saturated thickness exceeding 15 feet would remove COC mass and ultimately reduce flux to the south by reducing the gradient and thus the driving head of affected water movement into this area. Experience with the SEPTS has shown that wells with lower flow rates can, over time, provide demonstrable positive impacts for remediation of the perched groundwater. Pump testing conducted in 2015 indicates that the perched aquifer in the vicinity of PTX06-1147 can support extraction at flow rates in the range of 3 to 4 gpm.

Assuming that the current SEPTS conveyance system lines could be used, the cost per unit mass removal of extending the SEPTS east of FM 2373 would be significantly lower than installing an in-situ treatment system. Additionally, the Pantex Renewable Energy Project can provide some of the needed infrastructure for power to these extraction wells. Therefore, it is recommended that Pantex continue with plans to extend the SEPTS into this area.

In addition, the recent increase of water levels in PTX06-1133A combined with the discovery of almost seven feet of saturation at PTX06-1182 and the presence of RDX in both wells presents several questions regarding the extent of perched groundwater and contaminants in this area. Pantex is currently installing additional downgradient wells to determine perched groundwater and contaminant extent.
